

Greenscreen AI Data prep

Hi! Thanks for helping with this project! Here's a handy guide to the style and format of data I need!

Folder Structure

Clip#### <- Master folder containing frames of clip, numbered

- Input <- Foreground object on Greenscreen
- FG <- Foreground object on black (greenscreen background invisible to camera)
- BG <- Background, but with foreground object made invisible to camera
- Alpha - The alpha channel of the foreground object

Examples of render passes

IMPORTANT: BG pass should be a pixel-perfect match to Input for any areas not obscured by the foreground object. In other words, the FG object still needs to interact with the lighting simulation (shadows, bounce light, reflections). The FG object's visibility should only be hidden from the camera, not from the lighting.

Likewise, when generating the FG, make the background invisible to camera, but keep it on for lighting interactions..

Input

FG

BG

Alpha

~~FG object Lighting Nuance. Important!~~

~~When making the background invisible to camera, we don't want to make it invisible to the lighting. A lot of very important bounce light still comes off of a greenscreen, and removing the element from lighting calculations leads to a physically incorrect lack of ambient lighting on the FG object. To solve this, try turning the greenscreen GRAY and making it only invisible to the camera, when rendering out the FG object. This way it will still provide bounce light in the scene, but the green tint of the bounce light will be replaced by the neutral gray bounce light.~~

~~What about transparent objects like glass? You might need to turn off your background completely to get correct transparency. Use your best judgement and go with what visually looks the best to you as an artist. What do you think a perfect greenscreen key of your transparent object would look like? Proceed with that.~~

IGNORE THIS PAGE!

File format and color space requirements

I need:

EXRs in 32 bit depth, DWAB compression, 2048x2048 resolution. (might upgrade to 4096x4096 later if this experiment works!)

sRGB color Gamut, Linear Gamma.

48 frame clips! No longer than 48 and please no shorter than 24.

Linear gamma is very important! If you render out at 2.2 Gamma or 2.4 Gamma I can correct it later, but it's a hassle!

SANITY CHECK

Are your render passes being calculated correctly? Here's how you can check!

Take your FG pass (RGB only, Foreground object on black). Apply the alpha channel you rendered separately to the A channel.

Put the FG with alpha channel on top of your BG channel.

This should give you a 1:1 match with the input image, ~~(excluding the change in bounce light, if you tinted the screen gray for the FG renders)~~
